Projects

In my **astrophysical** research, I am primarily interested in how the gas in galaxies constantly rearranges itself over huge time spans to constantly form new stars, and in bringing large data sets and new data science techniques to bear on understanding the structure of the Milky Way. I have also had a long-standing interest in **data visualization**, and in improving the use of computers in all aspects of modern **(21st century) scholarship** and scientific research. My interests in astronomy, visualization, and 21st-century tools combine in the form of WorldWide Telescope, which I help create and maintain, and upon which the WorldWide Telescope Ambassadors **science education** Program I founded often relies. Since 2014, I have become very interested in the history of **Prediction**, as a way to understand modern computer simulations and their interpretation. I have served as coDirector for Science, where I help to bring new scholarship across the sciences to the attention of scholars and the public, at **Radcliffe** since 2017. Someday soon, I may perhaps find time to make custom webpages for each of my interest areas below, but for now, please do follow the links, as many of the projects have entire websites of their own.

Presentations associated with all of the projects below can be found at the [Talks Page](#).

ABSTRACT

We present a uniform catalog of accurate distances to local molecular clouds informed by the Gaia DR2 data release. Our methodology builds on that of Schlafly et al. (2014). First, we infer the distance and extinction to stars along sightlines towards the clouds using optical and near-infrared photometry. When available, we incorporate knowledge of the stellar distances obtained from Gaia DR2 parallax measurements. We model these per-star distance-extinction estimates as being caused by a dust screen with a 2-D morphology derived from Planck at an unknown distance, which we then fit for using a nested sampling algorithm. We provide updated distances to the Schlafly et al. (2014) sightlines towards the Dame et al. (2001) and Magnani et al. (1985) clouds, finding good agreement with the earlier work. For a subset of 27 clouds, we construct interactive pixelated distance maps to further study detailed cloud structure, and find several clouds which display clear distance gradients and/or

 Abstract
 We present a new technique to determine distances to major star-forming regions across the Perseus Molecular Cloud, using a combination of stellar photometry, astrometric data, and ¹²CO spectral line energy distribution (SLED) measurements. Incorporating the Gaia DR2 parallax measurements when available, we start by identifying the distance and reddening to stars from their Gaia DR2 and 2MASS photometry, then use a technique presented in Zucker et al. (2017, 2015) and implemented in their 3D “Reverber” dust map of observations of the sky. We then refine the Zucker et al. technique by using the velocity structure of a CO spectral cube to that template and modeling the contamination distribution of dust along the line of sight towards these stars as a linear combination of the members in the slice. Using a nested sampling algorithm, we fit these per-star distance-reddening measurements to find the distance to the CO velocity slice towards each star-forming region. This results in distance estimates typically tied to the velocity structure of the molecular gas. We determine distances to the B5, IC348, B1, NGC1333, L1448, and L1451 star-forming regions and find that individual stars are located between ~275 – 300 pc, with typical combined uncertainties of ~10%. We find that the velocity gradient across Perseus corresponds to a distance gradient of about 20 pc, with the eastern portion of the cloud farther away than the western portion. We determine an average distance to the complex of 20 ± 2 pc, about 80 pc higher than the distance derived to the nearest portion of the cloud using parallax measurements of stars nearby associated with young stellar objects. The method we present in our paper for the Perseus Complex, but may be applied elsewhere on the sky with adequate CO data in the presence of more accurate 3D maps of molecular clouds in the same neighborhood and beyond.

 Abstract
 We present a new technique to determine distances to major star-forming regions across the Perseus Molecular Cloud, using a combination of stellar photometry, astrometry data, and ¹³CO spectral line energy distribution (SLED) profiles. Incorporating the Gaia DR2 parallax measurements when available, we start by identifying the distance and reddening to stars from their ¹³CO SLEDs and DR2 parallaxes. We then use a technique presented in Giannini et al. (2011, 2017) and implemented in their 3D-REDASTER dust map of observations of the sky. We then reduce the Giannini et al. technique by using the velocity slices of a CO spectral cube to that technique and weighting the cumulative distribution of stars along the line of sight towards their stars as a linear combination of the masses in the stars. Using a nearest neighbor algorithm, we fit these parallax distance-estimating measurements to find the distance to the CO velocity slice closest to each star-forming region. This results in distance estimates typically tied to the velocity structure of the molecular gas. We determine distances to the B5, IC348, B1, NGC1333, L1448, and L1451 star-forming regions and find that individual clouds are located between ~275 – 300 pc, with typical standard uncertainties of ~10 pc. We find that the velocity gradient across Perseus corresponds to a distance gradient of about 20 pc, with the eastern portion of the cloud farther away than the western portion. We determine an average distance to the complex of 281 ± 27 pc, about 80 pc higher than the distance derived to the eastern portion of the cloud using parallax measurements of stars nearby associated with young stellar objects. The method we present in our paper for the Perseus Complex has many implications for the study of subsequent CO data in the presence of more accurate 3D maps of molecular clouds in the wider neighborhood and beyond.

→ ESA'S FLEET ACROSS THE SPECTRUM

Thanks to cutting edge technology, astronomy is unveiling a new world around us. With ESA's fleet of spacecraft, we can explore the full spectrum of light and probe the fundamental physics that underlies our entire Universe. From cool and dusty star formation revealed only at infrared wavelengths, to hot and violent high-energy phenomena, ESA missions are charting our cosmos and even looking back to the dawn of time to discover more about our place in space.

 Abstract
 We present a new technique to determine distances to major star-forming regions across the Perseus Molecular Cloud, using a combination of stellar photometry, astrometric data, and CO spectral line energy distributions (SLEDs). Incorporating the Gaia DR2 parallax measurements when available, we start by identifying the distance and reddening to stars from their ¹²CO(2-1) and ¹³CO(2-1) SLEDs. Then, using a technique presented in Zucker et al. (2018, 2017) and implemented in their 3D “Reverber” dust map of observations of the sky. We then refine the Zucker et al. technique by using the velocity structure of a CO spectral cube to constrain and model the contamination distribution of stars along the line of sight towards these stars as a linear combination of the members in the sky. Using a novel sampling algorithm, we fit these parallax distance-estimating measurements to find the distance to the CO velocity structure towards each star-forming region. This results in distance estimates typically tied to the velocity structure of the molecular gas. We determine distances to the B5, IC348, B1, NGC1333, L1448, and L1451 star-forming regions and find that individual stars are located between ~275 – 300 pc, with typical combined uncertainties of ~25%. We find that the velocity gradient across Perseus corresponds to a distance gradient of about 20 pc, with the nearest portion of the cloud farther away than the western portion. We determine an average distance to the complex of 293 ± 27 pc, about 80 pc higher than the distance derived to the nearest portion of the cloud using parallax measurements of stars nearby associated with young stellar objects. The method we present in our paper for the Perseus Complex has many implications for the study of subsequent CO data in the presence of more accurate 3D maps of molecular clouds in the wider neighborhood and beyond.

 Abstract
 We present a new technique to determine distances to major star-forming regions across the Perseus Molecular Cloud, using a combination of stellar photometry, astrometry, dust, and ¹²C/¹³C spectral line ratios. Incorporating the Gaia DR2 parallax measurements when available, we start by inferring the distance and reddening to star-forming regions from CO(2-1) and CO(3-2) observations. Next, we use a technique presented in Zucker et al. (2018, 2017) and implemented in their 3D-RECONSTRUCT tool to map the three-dimensional structure of the cloud. We then refine the Zucker et al. technique by using the velocity structure of a CO spectral cube to map temperature and modeling the orientation distribution of dust along the line-of-sight towards star-forming regions as a linear combination of the distance to the stars. Using a nearest neighbor algorithm, we fit these parallax distance-estimating measurements to find the distance to the CO velocity structure across the star-forming regions. This results in distance estimates typically tied to the velocity structure of the molecular gas. We determine distances to the B5, IC348, B1, NGC1333, L1448, and L1451 star-forming regions and find that individual clouds are located between ~275 – 300 pc, with typical standard uncertainties of ~25%. We find that the velocity gradient across Perseus corresponds to a distance gradient of about 20 pc, with the nearest portion of the cloud farther away than the western portion. We determine an average distance to the complex of 281 ± 27 pc, about 60 pc higher than the distance derived to the nearest portion of the cloud using parallax measurements of main-sequence stars using stellar spectroscopy. The method we present in our paper for the Perseus Complex has many implications for other star-forming regions. CO data in the presence of more accurate 3D maps of molecular clouds in the wider neighborhood and beyond.

How we did this.

ABSTRACT

We present a uniform catalog of accurate distances to local molecular clouds informed by the Gaia DR2 data release. Our methodology builds on that of Schlafly et al. (2014). First, we infer the distance and extinction to stars along sightlines towards the clouds using optical and near-infrared photometry. When available, we incorporate knowledge of the stellar distances obtained from Gaia DR2 parallax measurements. We model these pre-star distance-extinction estimates as being caused by a dust screen with a 2-D morphology derived from Planck at an unknown distance, which we then fit for using a nested sampling algorithm. We provide updated distances to the Schlafly et al. (2014) sightlines towards the Dame et al. (2001) and Magiani et al. (1985) clouds, finding good agreement with the earlier work. For a subset of 27 clouds, we construct interactive pixelated distance maps to further study detailed cloud structure, and find several clouds which display clear distance gradients and/or are comprised of multiple components. We use these maps to determine robust average distances to these clouds. The characteristic combined uncertainty on our distances is $\approx 5 - 6\%$, though this can be higher for clouds at farther distances, due to the limitations of our single-cloud model.
